# Genome-wide association analysis identified splicing single nucleotide polymorphism in CFLAR predictive of triptolide chemo-sensitivity

Lata Chauhan<sup>1</sup>, Gregory D. Jenkins<sup>2</sup>, Neha Bhise<sup>3</sup>, Tanya Feldberg<sup>3</sup>, Taraswi Mitra-Ghosh<sup>3</sup>, Brooke L. Fridley<sup>4</sup> and Jatinder K. Lamba<sup>1\*</sup>

## Abstract

**Background:** Triptolide is a therapeutic diterpenoid derived from the Chinese herb *Tripterygium wilfordii* Hook f. Triptolide has been shown to induce apoptosis by activation of pro-apoptotic proteins, inhibiting NFκB and c-KIT pathways, suppressing the Jak2 transcription, activating MAPK8/JNK signaling and modulating the heat shock responses.

**Results:** In the present study, we used lymphoblast cell lines (LCLs) derived from 55 unrelated Caucasian subjects to identify genetic markers predictive of cellular sensitivity to triptolide using genome wide association study. Our results identified SNPs on chromosome 2 associated with triptolide IC<sub>50</sub> (p < 0.0001). This region included biologically interesting genes as CFLAR, PPII3, Caspase 8/10, NFκB and STAT6. Identification of a splicing-SNP rs10190751, which regulates CFLAR alternatively spliced isoforms predictive of the triptolide cytotoxicity suggests its role in triptolides action. Our results from functional studies in Panc-1 cell lines further demonstrate potential role of CFLAR in triptolide toxicity. Analysis of gene-expression with cytotoxicity identified JAK1 expression to be a significant predictor of triptolide sensitivity.

**Conclusions:** Overall our results identified genetic factors associated with triptolide chemo-sensitivity thereby opening up opportunities to better understand its mechanism of action as well as utilize these biomarkers to predict therapeutic response in patients.

**Keywords:** Triptolide, Genome-wide association studies, Hap-map, Single nucleotide polymorphisms, CFLAR

## Background

Triptolide is a biological diterpenoid derived from the Chinese herb *Tripterygium wilfordii* HOOK f. Triptolide has been shown to have anti-inflammatory and immunosuppressive activities and has been used in traditional Chinese medicine to treat several diseases, such as, rheumatoid arthritis, immune complex diseases, and systemic lupus erythematosus [1, 2]. It has been shown to have influence on several anti-tumor target genes and inhibit tumors by altering multiple signaling pathways, such as, inhibition of NFκB and c-KIT pathway [3], inhibition of Jak2 transcription [4], inducing apoptotic

signals by activation of pro-apoptotic proteins [5, 6], activation of MAPK8/JNK [5, 6], and inhibition of heat shock response [7, 8]. Triptolide has also been shown to influence epigenetic modulation of genes by interaction with histone methyltransferase and demethylase [9]. In spite of the wide therapeutic properties of triptolide, poor water solubility has limited its clinical use in the past. However, recently a water-soluble analog of triptolide—Minnelide has shown promising results in pancreatic cancer cell lines, human xenograft models, as well as in mouse models of pancreatic cancer [10]. Minnelide has been shown to reduce tumor burden in preclinical models of osteosarcoma [11]. Taken together with the anti-tumor properties of triptolide and the recent development of triptolide analogs to overcome its water

Full list of author information is available at the end of the article

solubility, triptolide has emerged as a promising anti-tumor agent.

In the present study, we evaluated the impact of genetic variations and gene expression profiles predictive of triptolide cytotoxicity using Epstein-Barr-virus transformed lymphoblastoid cell lines (LCLs) that are part of International HapMap project ([www.hapMap.org](http://www.hapMap.org)) [12]. HapMap LCLs has been used as model to identify genetic markers associated with in vitro chemo-sensitivity to several drugs [13–16]. Genotype data is publically available allowing for genome-wide association analyses for biomarker identification. Our results validated some of the known genes/pathways as well as identified novel candidate genes/pathways of relevance to triptolide. We further validated the functional significance of CFLAR in pancreatic cell lines.

## Methods

### In vitro cytotoxicity assays

HapMap LCLs from subjects with European ancestry (CEU; n = 55 unrelated) were obtained from the Coriell Institute for Medical Research and were maintained as recommended. In vitro cytotoxicity was determined by treating LCLs with varying concentrations of triptolide (500, 50, 20, 10, 6.67, 1.3 and 0 nM) for 48 hr followed by cell viability measurements using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assays (Life Technologies, USA) and Synergy 5 multi-plate reader. Cytotoxicity assays were performed in duplicates and cell lines were randomly chosen to repeat on different dates to rule out any experimental variation. Panc-1, a pancreatic cell line (ATCC, USA) was used for functional validation of the top gene identified in the GWAS. Panc-1 was cultured in DMEM medium supplemented with 2 mM glutamine and 10 % fetal bovine serum.

### Real-time quantitative PCR analysis

mRNA expression levels of CFLAR spliced isoforms were quantitated in LCLs and Panc-1 cell lines using CFLAR isoform specific oligonucleotide primers and  $2^{-\Delta\Delta CT}$  method as described in Additional file 1 and Fig. 2.

### Genotyping of panc-1 cell lines

Genomic DNA from Panc-1 cell line was genotyped for CFLAR SNP rs10190751 (A/G) using TaqMan SNP genotyping assay (Applied Biosystems, Foster City, CA, USA). Genomic DNAs from HapMap cell lines with known genotype (AA, AG and GG) were used as controls.

### Western blotting

Western plotting was performed using whole-cell lysates and CFLAR (Enzo lifesciences) or  $\beta$ -actin (Abcam) primary and mouse IgG secondary antibodies.

### siRNA mediated knockdown of CFLAR in cancer cell lines

Mission esiRNA were procured from Sigma Aldrich. esiRNA were synthesized through in vitro transcription of a 300–600 bp gene specific dsRNA, which is further digested in to complex pool of siRNA using RNases. This digested pools of esiRNA are verified by DNA sequencing and gel electrophoresis to ensure identity and high specificity (Sigma Aldrich). To ensure high specificity and efficacy of the esiRNA, the algorithm DEQOR is utilized (Design and Quality Control of RNAi, available to the public via [http://deqor.mpi-cbg.de/deqor\\_new/input.html](http://deqor.mpi-cbg.de/deqor_new/input.html)). CFLAR specific 424 base pair sequence used in this study to create esiRNA pool for CFLAR knock-down is “TCCATCAGGTTGAAGAAGCACTTG ATA CAGATGAGAAGGAGATGCTGCTCTTTTTGTGCC GGGATGTTGCTATAGATGTGGTTCCACCTAATGTC AGGGACCTTCTGGATATTTTACGGGAAAGAGGT AAGCTGTCTGTCGGGGACTTGGCTGAACTGCTC TACAGAGTGAGGCGATTGACCTGCTCAAACGTA TCTTGAAGATGGACAGAAAAGCTGTGGAGACCC ACCTGCTCAGGAACCCTCACCTTGTTCGGACT ATAGAGTGCTGATGGCAGAGATTGGTGAGGATT TGGATAAATCTGATGTGTCCCTCATTAATTTTCTT CATGAAGGATTACATGGGCCGAGGCAAGATAAGC AAGGAGAAGAGTTTCTTGGACCTTGTGGTTGAGT TGGAGAACTAAATCTGGTTGCCCCAGA”.

Panc-1 cells were transfected with 200 nM CFLAR-esiRNA and negative siRNA using Lipofectamine® 2000 (Life technologies) as per manufacturer’s protocol. Twenty-four hours post-transfections cell were treated with varying concentrations of triptolide and cell viability was determined 48 hr post-treatment using MTT assays. mRNA levels of all three isoforms of CFLAR siRNA were quantitated 24 hr post-transfection to check for the knockdown.

### Transfection of CFLAR-Short and CFLAR-Long plasmid in Panc-1 cell line

Panc-1 cells were transfected with control and CFLAR expression plasmids (pEF6-V5, pEF-Flag A, pEF6-V5-CFLAR-S and pEF-Flag A-CFLAR-L) using Fugene HD reagent (Promega) followed by triptolide treatment and MTT assay as described above. Cell pellets were also collected for protein analysis.

### Statistical analysis

As these cell lines are part of several publically available genotyping databases, genotype data was retrieved on all cell lines from the HapMap project (release 23). For 29 samples, data was also retrieved from the 1000 genomes project (20101123 version). mRNA expression was retrieved for all of the individuals from a publically available source (<http://www.sanger.ac.uk/research/areas/humangenetics/>).  $IC_{50}$ , concentration that kills 50 % of the

cells, was calculated from a 4-parameter logistic model using the package *drc* v2.2.1 in R v2.14.0 [17].

#### Association analysis of triptolide cytotoxicity with genetic variation

SNP genotype ( $n = 4098136$ ) data was retrieved from the HapMap (release 23) for all 55 samples (29 female and 26 male). SNPs were filtered using various quality control criteria as, build changes, call rate, compliance with Hardy Weinberg and minimum allele frequency (MAF) as described in Additional file 1. In total 1978803 SNPs in 55 individuals passed quality control measures. For genotype data for individuals in the 1000 genomes only a MAF filter was used, dropping SNPs with  $MAF < 0.05$ . Several SNPs overlap between the 1000 genomes and HapMap data, data obtained from the 1000 genomes project was used preferentially over data obtained from the HapMap. Since not all of the samples used have been sequenced as part of the 1000 genomes project as of current, SNPs in the 1000 genomes project, but not in HapMap (release 23) were imputed for samples not included in the 1000 genomes project. BEAGLE v3.3.1 [18] was used to impute SNPs with the reference of the 1000 genomes as described in Additional file 1.

#### Association analysis of triptolide cytotoxicity with gene expression variation

mRNA expression from the Illumina Sentrix Human-6 Expression BeadChip version 1 was normalized as per Stranger et al., using 47293 probes [19]. For this analysis, only the Caucasian samples were used and data was normalized using quantile normalization across replicates and median normalization across individuals. Original Illumina annotation was retrieved from ReMOAT [20]. Expression was not adjusted for gender (did not appear to affect association with phenotypes).

#### Integrative analyses

With the wealth of data produced by current genomic technologies, collection of multiple types of genomic data on a set of samples is becoming commonplace. New methods explore a multifactor approach that combine different kinds of genomic data, sometimes referred to as “integrative genomics” or “genomic convergence”, in which a multistep procedure is used to identify potential key drivers of complex traits that integrate DNA variation and gene expression data. To integrate the genotype, expression and drug cytotoxicity data, we first identified markers associated with triptolide  $IC_{50}$  using a liberal significance threshold of 0.001. Next, we determined which expression probe sets were associated with these  $IC_{50}$  associated SNPs ( $p$ -values  $\leq 10^{-5}$ ) (i.e., eQTLs). Finally, to determine whether the expression probe sets associated with these SNPs were also associated with

triptolide  $IC_{50}$  values, we identified which expression probe sets were associated with  $IC_{50}$  with a  $p$ -values  $\leq 0.0001$ . A similar integrative analysis approach has been used successfully to detect novel candidate genes [21]. The association between  $IC_{50}$  and SNP genotypes modeled as count of rare alleles (additive genetic model), or  $\log_2$  normalized mRNA expression and cytotoxicity phenotypes, or SNPs was quantified using a spearman correlation coefficient, and  $p$ -value calculated for the null hypothesis of no association using an F-test.

## Results

### Genetic associations with triptolide $IC_{50}$ in LCLs

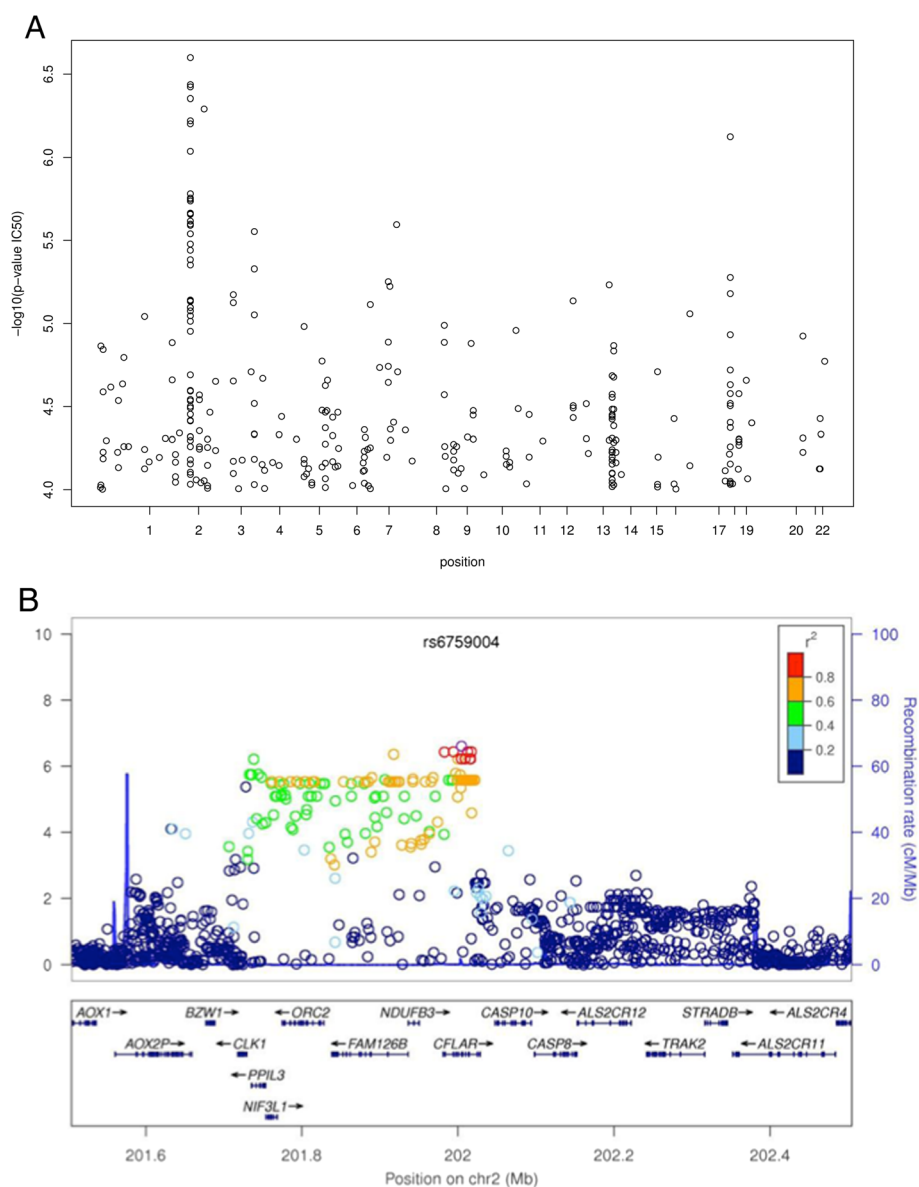

We evaluated 55 LCLs derived from unrelated subjects with Caucasian ancestry for cellular sensitivity to triptolide. Triptolide  $IC_{50}$  values ranged from 4 to 34 nM indicating wide inter-individual variation in chemosensitivity. GWAS analysis identified 140 SNPs in 11 genes that were associated with triptolide  $IC_{50}$  at  $p < 10^{-5}$  (488 SNPs at  $p < 10^{-4}$ ; Fig. 1a). Significant proportion of SNPs (110 of 140: 78.6 %) clustered in  $\sim 293$  kb region on chromosome 2 (Table 1), which maps to multiple biologically interesting genes (Genes important for cell division and Cancer development) including *CFLAR*, *CLK1*, *FAM126B*, *NDUFB3*, *NIF3L1*, *ORC2* and *PP1L3* (Table 2; Fig. 1b). Other genes with significant SNPs included *TP53BP2* (chr 1), *MTSU2* (chr 13), *ZNF532* (chr18) and *FNDC3B* (chr 3). Ingenuity pathway analysis of these genes mapped them to 4 networks (Table 3). These networks are involved in Cellular Movement, Inflammatory Response, Cell-To-Cell Signaling and Interaction; Cell Death and Survival, Cellular Function and Maintenance, Molecular Transport; Cancer, Dermatological Diseases and Conditions, Developmental Disorder; Cellular Movement, Hematological System Development and Function, Immune Cell Trafficking and carbohydrate metabolism.

*CFLAR* (Caspase 8 and FADD like apoptosis regulator) with maximum number of most significant SNPs ( $n = 41$ ; due to high LD as shown in Additional file 2: Figure S1) codes for protein c-FLIP. c-FLIP regulates apoptosis and is structurally similar to caspase-8, however, lacks the caspase activity. It has been implicated as a crucial link between cell survival and cell death pathways in mammalian cells.

### Gene expression associations with triptolide $IC_{50}$ in LCLs

Genome-wide gene expression analysis identified 14 probes that were associated with triptolide  $IC_{50}$  ( $p < 0.0001$ , Additional file 3: Figure S2 and Table 4). Some of the biologically interesting genes with expression levels associated with triptolide sensitivity included: *JAK1* (Janus kinase 1), *DTX1* (Deltex Homolog 1; positive regulator of Notch signaling pathway), *AGL* (Amylo-Alpha-1, 6-Glucosidase, 4-Alpha-Glucanotransferase involved in glycogen degradation), and *MUC15* (Mucin 15, Cell

**Fig. 1** Genome-wide association study of SNPs with Triptolide cytotoxicity. **a** Manhattan plot showing association of SNPs with Triptolide  $IC_{50}$  (only SNPs with  $p < 10^{-4}$  are included). **b** Genomic region on Chr 2 with strongest association with triptolide cytotoxicity. Y-axis represents  $-\log_{10}$  (P value) and X-axis presents chromosomal location

Surface Associated). Pathway analysis using Ingenuity pathway analysis tool mapped these genes to JAK/STAT, IL, iNOS, EGFSignaling pathways (Additional file 4: Figure S3).

**Integrated SNP-mRNA association analysis with  $IC_{50}$**

We performed integrated analysis between SNPs-mRNA expression- $IC_{50}$ ; we selected top SNPs that were significantly ( $p < 0.001$ ) associated with cytotoxicity, and top gene expression signatures significantly ( $p < 0.001$ ) associated with cytotoxicity for association with each other i.e. SNP vs. gene expression. This analysis basically identified

eQTLs associated with triptolide  $IC_{50}$  and at  $p < 0.0001$  we identified 648 unique SNP-mRNA pairs that were associated with triptolide cytotoxicity however these SNP-mRNA pairs mapped to only 28 genes (Table 5), indicating association of multiple SNPs with one gene (which might be due to LD between SNPs). Some of the biologically interesting SNP-mRNA pairs included: association of multiple SNPs in chromosome 16 spanning genes CHST5, TMEM231, GABARAPL2 and ADAT1 with expression levels of AGL; SNPs in ASXL3 with ASCL4 expression; CAMTA1 SNPs and CRYGS expression; TIAM1 SNPs with DTX1 expression; SNPs in

GPATCH1, and multiple SNPs on chr 5 and 14 with JAK1 expression. Multiple SNPs within CFLAR were associated with expression levels of MTVR1, PIP5K1B and C9orf19/GLRIP2.

#### Functional significance of CFLAR splicing SNP

We selected CFLAR for functional validation in our study on the basis of following observations; i) higher number of SNPs in CFLAR were associated with the triptolide cytotoxicity (Tables 1 and 2); ii) CFLAR. SNP-mRNA pairs associated with triptolide cytotoxicity included three CFLAR mRNA probes additionally multiple SNPs within CFLAR were associated with each 3 mRNA probes. Majority of the significantly associated SNPs within CFLAR gene were intronic and occurred in high LD (Additional file 2: Figure S1). However, one CFLAR SNP, rs10190751 G > A, was present at the splice junction of exon 7 (Fig. 2a) and was significantly associated with triptolide cytotoxicity (Fig. 2b). We screened HapMap cell lines with AA, AG and GG genotype (3 cell lines in each genotype group) for long (CFLAR-L), short (CFLAR-S) and raji (CFLAR-R) forms of CFLAR splice variants. CFLAR-L form was present in all cell lines irrespective of the genotype whereas CFLAR-S form was only expressed in cell lines with at least one G allele (Fig. 3a). Real-time quantification of CFLAR splice variants showed significant association of AA genotype with low levels of CFLAR-L; complete absence of CFLAR-S and higher levels of CFLAR-R form (Fig. 3). Western blot analysis confirmed the association of C-FLIP protein isoform levels corresponding to rs10190751 genotype and CFLAR mRNA isoforms (Fig. 3c).

#### siRNA mediated functional studies on CFLAR

We selected Panc-1 for further investigation for impact of siRNA mediated transient knockdown of CFLAR on cellular sensitivity to triptolide. We selected Panc-1 for further investigation for impact of siRNA mediated transient knockdown of CFLAR on cellular sensitivity to triptolide. Panc-1 was selected based on the literature evidence of efficient use of triptolide in pancreatic cancer at pre-clinical and clinical level [Ref] as well as

CFLAR being reported as a therapeutic target for triptolide in Pancreatic cancer [ref]. Genotype of Panc-1 for rs10190751, was identified as GG, therefore all isoform of CFLAR expressed in this cell line and it makes this cell line a perfect model to do functional validation for different isoform. In a pancreatic cancer cell line, Panc-1, siRNA mediated knockdown resulted in significant reduction in the CFLAR-L, CFLAR-S and CFLAR-R isoforms and significant increase in sensitivity to, triptolide (Fig. 4a and b).

#### Over expression of CFLAR-long and short isoform

Since Panc-1 demonstrated change in chemo-sensitivity in siRNA mediated knockdown of CFLAR, we further overexpressed CFLAR-L and CFLAR-S forms in Panc-1 cell lines. Transient transfection of most abundant isoforms of CFLAR was done in Panc-1 cell line using pEFA-CFLAR-L and pEF6-V5-CFLAR-L plasmid for Long and Short form of CFLAR respectively. Compared to cells transfected with control plasmids the level of CFLAR protein isoforms were significantly increased (Fig. 4c). Over-expression CFLAR-L or CFLAR-S isoforms resulted in significant decrease in sensitivity for triptolide, (Fig. 4d).

#### Discussion

Triptolide is a diterpenoid triepoxide and has been used in traditional Chinese medicine for years. Poor water solubility and toxicity has limited its use in clinics, however recent advances focused on developing triptolide derivatives with better solubility such as MC002 [22], omtritolide [23], minnelide [10] etc. are showing promising advancements especially in pancreatic cancer. The anticancer activity of triptolide has been associated with its ability to inhibit various pro-proliferative or anti-apoptotic factors thereby inducing apoptosis [16]. Triptolide has been implicated in activation of both intrinsic and extrinsic apoptotic pathways by inducing caspase-8, -9 and 3 as well as by inducing cleavage of PARP [24, 25]. Given the fact that triptolide has a promising potential as a therapeutic agent, we designed this study to identify the

**Table 2** Summary of genes with SNPs significantly associated ( $p < 0.00001$ ) with triptolide cytotoxicity in HapMAP LCLs

Gene Symbol	Gene full name	Gene summary (Ref gene)	# of SNPs at $p < 0.00001$
CFLAR	Caspase 8 and FADD-like apoptosis regulator	The protein encoded by this gene is a regulator of apoptosis and is structurally similar to caspase-8. However, the encoded protein lacks caspase activity and appears to be itself cleaved into two peptides by caspase-8. Several transcript variants encoding different isoforms have been found for this gene, and partial evidence for several more variants exists	45
FAM126B	Family With Sequence Similarity 126, Member B		22
PPIL3	Peptidylprolyl isomerase 9(cyclophilin)-like 3	This gene encodes a member of the cyclophilin family. Cyclophilins catalyze the cis-trans isomerization of peptidylprolyl imide bonds in oligopeptides. They have been proposed to act either as catalysts or as molecular chaperones in protein-folding events. Alternative splicing results in multiple transcript variants. PPIases accelerate the folding of proteins. It catalyzes the cis-trans isomerization of proline imidic peptide bonds in oligopeptides.	7
ZNF532			2
NDUFB3	NADH dehydrogenase (ubiquinone0 1beta subcomplex,3, 12kD	This gene encodes an accessory subunit of the mitochondrial membrane respiratory chain NADH dehydrogenase (Complex I) which is the first enzyme in the electron transport chain of mitochondria. This protein localizes to the inner membrane of the mitochondrion as a single-pass membrane protein. Mutations in this gene contribute to mitochondrial complex I deficiency	3
NIF3L1	NIF3 NGG1 interacting factor 3-like 1( <i>S. cerevisiae</i> )	Functions as transcriptional corepressor	11
ORC2	Origin recognition complex subunit 2	The origin recognition complex (ORC) is a highly conserved six subunits protein complex essential for the initiation of the DNA replication in eukaryotic cells. Studies in yeast demonstrated that ORC binds specifically to origins of replication and serves as a platform for the assembly of additional initiation factors such as Cdc6 and Mcm proteins. The protein encoded by this gene is a subunit of the ORC complex. This protein forms a core complex with ORC3, -4, and -5. It also interacts with CDC45 and MCM10, which are proteins known to be important for the initiation of DNA replication.	20
CLK1	CDC-like kinase 1	This gene encodes a member of the CDC2-like (or LAMMER) family of dual specificity protein kinases. In the nucleus, the encoded protein phosphorylates serine/arginine-rich proteins involved in pre-mRNA processing, releasing them into the nucleoplasm. The choice of splice sites during pre-mRNA processing may be regulated by the concentration of transacting factors, including serine/arginine rich proteins. Therefore, the encoded protein may play an indirect role in governing splice site selection. Phosphorylates: SRSF1, SRSF3 and PTPN1. Regulates the alternative splicing of tissue factor (F3) pre-mRNA in endothelial cells and adenovirus E1A pre-mRNA	1
CSMD1	CUB and Sushi multiple domains 1		1
FNDC3B	fibronectin type III domain containing 3B		15
MTUS2	microtubule associated tumor suppressor candidate 2	Binds microtubules. Together with MAPRE1 may target the microtubule depolymerase KIF2C to the plus-end of microtubules. May regulate the dynamics of microtubules at their growing distal tip	1
TP53BP2	tumor protein p53 binding protein, 2	This gene encodes a member of the ASPP (apoptosis-stimulating protein of p53) family of p53 interacting proteins. The protein contains four ankyrin repeats and an SH3 domain involved in protein-protein interactions. It is localized to the perinuclear region of the cytoplasm, and regulates apoptosis and cell growth through interactions with other regulatory molecules including members of the p53 family. It plays central role in regulation of apoptosis and cell growth via its interactions. Regulates TP53 by enhancing the DNA binding and transactivation function of TP53 on the promoters of proapoptotic genes in vivo. Inhibits the ability of APPBP1 to conjugate NEDD8 to CUL1, and thereby decreases APPBP1 ability to induce apoptosis. Impedes cell cycle progression at G2/M. Its apoptosis-stimulating activity is inhibited by its interaction with DDX42	1

genomic markers associated with triptolide cytotoxicity using LCLs from International HapMap project.

Our results identified a QTL on chromosome 2 consisting of several SNPs with significant association with triptolide IC<sub>50</sub>. This region on chromosome 2 included biologically interesting genes such as CLK1, PPL3, NIF3L1, CFLAR, NDUFB3, CASP10, CASP8 etc. (Tables 1 and 2) with important roles in apoptosis and cell cycle regulation pathways. Of particular interest was significant over-representation the top most significant SNPs in CFLAR gene (Caspase 8 and FADD like apoptosis regulator). CFLAR gene encodes for protein c-FLIP, best-known for its anti-apoptotic regulatory role by inhibiting TNF-alpha, FAS-L and TRAIL induced apoptosis [26]. Although most of the SNPs in CFLAR were intronic, one splicing SNP,

rs10190751 (3' splice site of intron 6) was of particular interest [27]. CFLAR-protein, c-FILP exists in several isoforms due to alternate splicing, the most studied forms include long (C-FLIP-L) and short (C-FLIP-S) isoforms of 55 kD and 26 kD, respectively. CFLAR gene has 14 exons and inclusion or exclusion of intron 6 or exon 7 regulates the expression of long, or short or raji forms. CFLAR long form (CFLAR-L) skips exon 7 and is expressed as a full-length protein of 480 amino acids. CFLAR short form (CFLAR-S) includes exon 7 thereby changing the reading frame, creating an early stop codon, and hence a shorter isoform with 221 amino acids. C-FLIP-L is composed of two death effector domains (DEDs) at the amino terminus and a caspase homologous domain, structurally similar to caspase 8 and caspase 10 at carboxy terminus. In contrast

**Fig. 2** Schematic representation of CFLAR gene and its splice variants. **a** The schematic of CFLAR gene shows all the exons and the location of rs10190751 SNP at the 3' splice site of intron 6. Presence or absence of this SNP regulates production of CFLAR-short form (CFLAR-S). Difference splice variants of CFLAR are also shown along with the isoform specific primer pair's used in this study. **b** Box plot showing association of rs10190751 Splicing SNP with Triptolide LC<sub>50</sub> in HapMap LCLs. Y-axis is Log<sub>2</sub> Triptolide IC<sub>50</sub> and X-axis represents rs10190751 genotype. Box Plots show medians as a line between boxes representing the first and third quartiles; the whiskers represent the range after excluding outliers. The outliers are defined as data points that fall outside of the first and third quartiles by more than 1.5-times the interquartile range. Circles falling outside the whiskers represent outliers

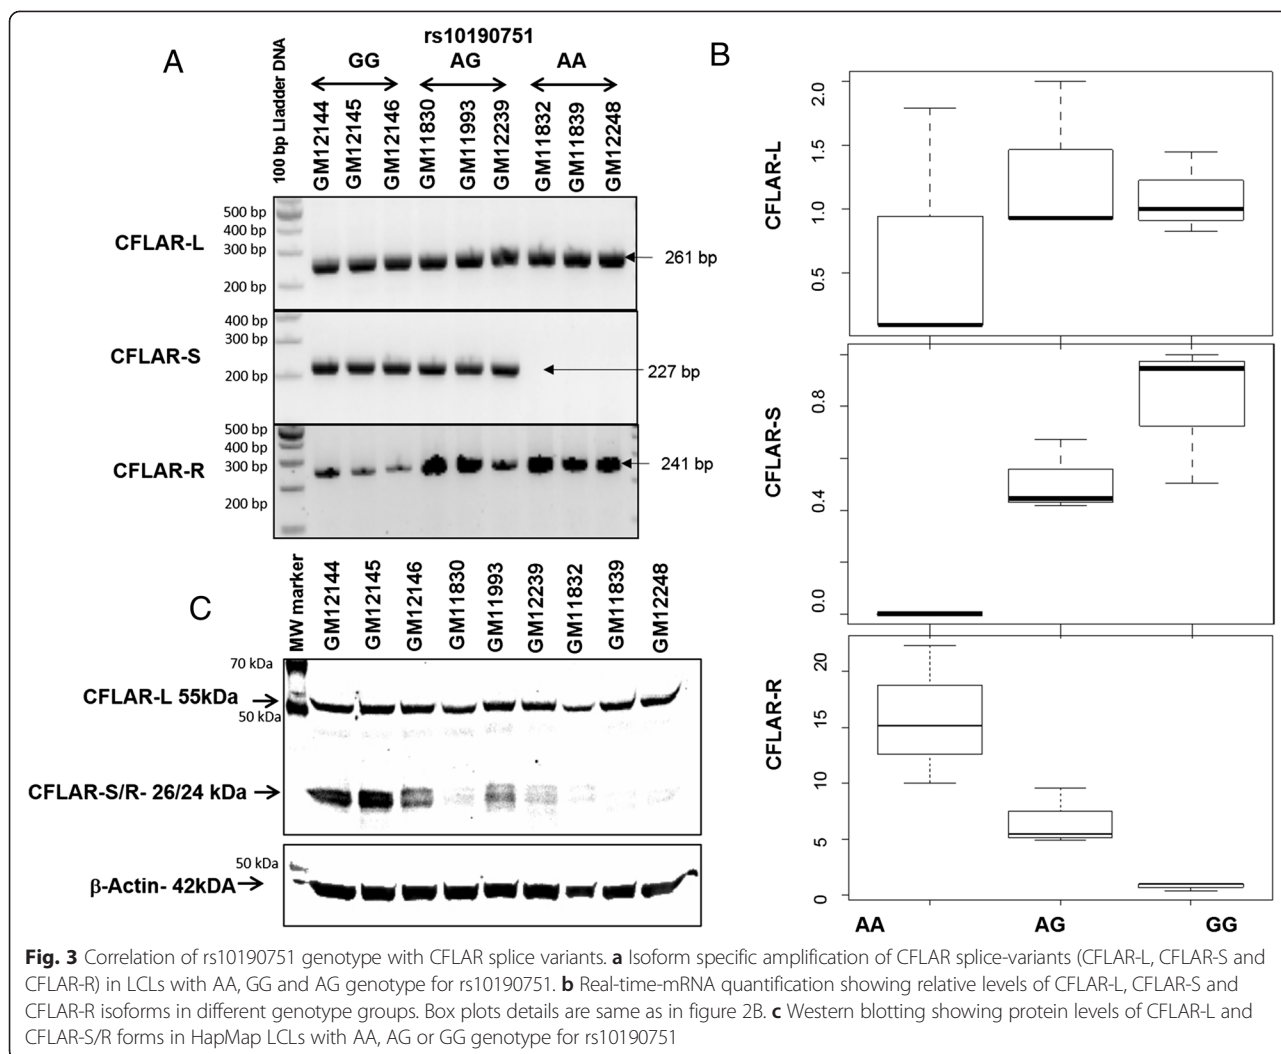

C-FLIP-S has two DEDs but lacks caspase homology domain. Presence of rs10190751 regulates the splicing event with rs10190751-A allele resulting in lack of expression of the short form (Fig. 4). In addition to these isoforms recently cFLIP-R forms has been identified in the Raji cells [27]. Due to intronic insertion; CFLAR-R isoform has a premature stop codon resulting in a protein with 212 amino acids and like the CFLAR-S isoform lacks caspase like domain.

Although the characterization of the functional differences of these isoforms is still ongoing, cell type specific pro-apoptotic role of CFLAR-L has been reported. CFLAR-L expression levels are considered critical factor in determining the balance between apoptotic and pro-survival signaling. The CFLAR-L has also been shown to play critical role in autophagy, necroptosis and apoptosis in T-lymphocytes with CFLAR-L deficiency triggering severe cell death upon stimulation [28]. In spite of its major role in regulating death receptor signaling, it has been shown to be involved in regulation of apoptosis by several other mechanism including; modulating the activity of ripoptosome [29] regulation of necroptosis

by preventing caspase 8 activation [30–32], inhibiting autophagosome formation by interfering with conjugation of LC3 and in NFκB signaling with its ectopic expression resulting in NFκB activation [33–35].

Given the important role of CFLAR (CFLIP) as a key inhibitor of processing and activation of caspase 8; its prognostic and therapeutic relevance in AML [36] as well as in development of drug resistance [37] we designed this study to further explore the clinical significance of the CFLAR and its genetic variation especially the splicing SNP (regulating CFLAR-L and CFLAR-S forms) as biomarker of risk of disease as well as with development drug resistance. Our results of siRNA mediated knock down and overexpression of CFLAR in pancreatic cancer cell lines further provides evidence of its involvement in chemo-sensitivity to triptolide.

Gene expression levels of JAK1, AGL, and DTX1 genes, all involved in cell-to cell signaling (Additional file 4: Figure S3) has been associated with triptolide cytotoxicity analysis. JAK1, Janus Kinase 1 is involved in interferon-alpha/beta and -gamma signal transduction pathways and is a critical component of JAK/STAT

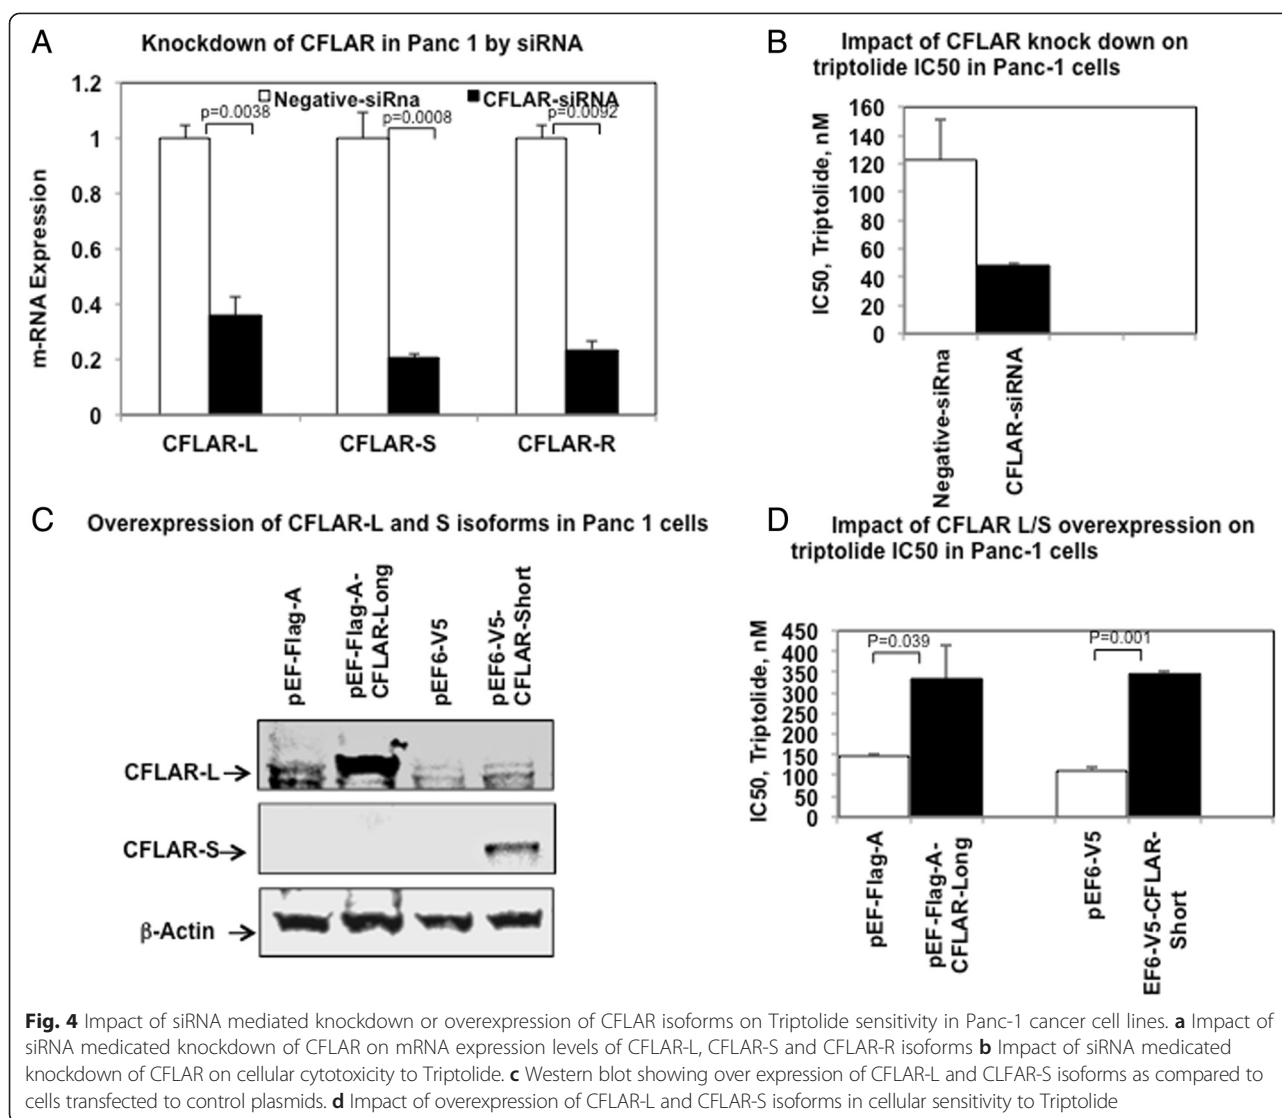

pathway; AGL is member of 4 alpha-glucanotransferase and is involved in glycogen degradation; DTX1, deltex homolog 1 is involved in NOTCH signaling pathway which is a critical for cell fate determination and has been implicated in several diseases as well as tumorigenesis [38]. In our integrative exploratory analysis we identified several biologically interesting gene-SNP-gene-expression pairs as TIAM1-DTX1, ASXL3: ASCL4, GPATCH2: JAK1, CAMPTA1-CRYGS, ERBB4-NADSYN1 etc.

In recent years there has been significant evidence suggesting triptolide mediated inhibition of ATPase activity of XPB, thereby by influencing transcription as well as Nucleotide excision repair [39]. XPB, also known as ERCC3 is a subunit of transcription factor TFIIH. Triptolide has been shown to influence gene expression by globally reducing gene expression although to not to same extent for all genes by blocking transcription initiation [40, 41]. Antiproliferative effects of triptolide due to inhibition of XPB/TFIIH has also been shown to phenocopy JNK-dependent apoptosis phenotype in Dp53

deficient wing disc cells in *Drosophila* [42]. This global reduction of transcription caused by triptolide, correlates well with the phenotypes observed in tumour cells and in inflammation. If we take in account these evidences, and if the treatment with triptolide, reduce global transcription, cells with reduction of the CFLAR mRNA isoforms by the splicing SNP will be even more sensitive, since this gene may negatively modulates apoptosis. The KD and overexpression results using Panc-1 cells incubated with triptolide may also be explained in part by taking in account a reduction in global transcription caused by triptolide.

In conclusion, our results identified CFLAR as an important predictor of triptolide cytotoxicity. Splicing SNP-rs10190751 regulates production of CFLAR- long and short isoforms, which are associated with triptolide cytotoxicity. The central role of anti-apoptotic protein c-FLIP (CFLAR product) in regulating death receptor signaling points to the fact that this splicing SNP might of importance to other chemotherapeutic agents. Up-

regulation of c-FLIP has been associated with poor clinical outcome and thus could be reliable prognostic factor for several types of cancer, however the significance of CFLAR genetic variation as predictor of therapeutic efficacy has not been explored so far, thus opening up opportunities for future studies.

## Conclusions

Triptolide being an emerging drug, provides us a reason to do a genome wide association study to identify specific genetic polymorphism which may affect triptolide induced cytotoxicity. We observed significant association of triptolide IC50 with SNPs located in biological important genes from apoptotic pathway, such as CFLAR, PP1L3, caspase 8/10, NfKb and STAT6. CFLAR is an upstream regulator of apoptotic pathway. Due to its important position as a regulator of apoptosis, we validated its functional role in triptolide induced cytotoxicity in

pancreatic cancer cell line. Our finding shows that CFLAR polymorphism plays important role in cancer cell death induced by triptolide. Further studies are needed to predict the therapeutic response in patients.

## Availability of supporting data

Gene expression data is publically available from Gene Expression Omnibus under submission number series: GSE6536. Genotype data is available at HapMap.org-release 23 ([www.HapMap.org](http://www.HapMap.org)).

## Additional files

**Additional file 1:** Supplementary Notes.

**Additional file 2: Figure S1.** LD plot generated using Haploview for chromosome 2 region flanking CFLAR gene in CEU population.

**Additional file 3: Figure S2.** Genome-wide association study of mRNA expression with Triptolide cytotoxicity. Y-axis represents  $-\log_{10}$  (P value) and X-axis presents chromosomal location.

**Additional file 4: Figure S3.** Overlapping networks identified by pathway analysis of genes identified in gene expression analysis with Triptolide IC<sub>50</sub> in HapMap LCLs using Ingenuity pathway analysis (IPA) tool.

#### Competing interests

The authors declare they have no competing interests.

#### Authors contributions

JKL, conceived the study design; LC, NB, TF and TMG performed the experiments; BLF and GDJ performed statistical analysis; All authors contributed to manuscript writing. All authors read and approved the final manuscript.

#### Acknowledgements

We are thankful to Professor Ingo Schmitz, (Helmholtz Center for Infection Research Inhoffenstr, Braunschweig, Germany) for providing CFLAR expression plasmids (pEF6-V5, pEF-Flag A, pEF6-V5-CFLAR-S and pEF-Flag A-CFLAR-L) and Dr. Gunda Georg for providing triptolide.
